

# Error reporting logic

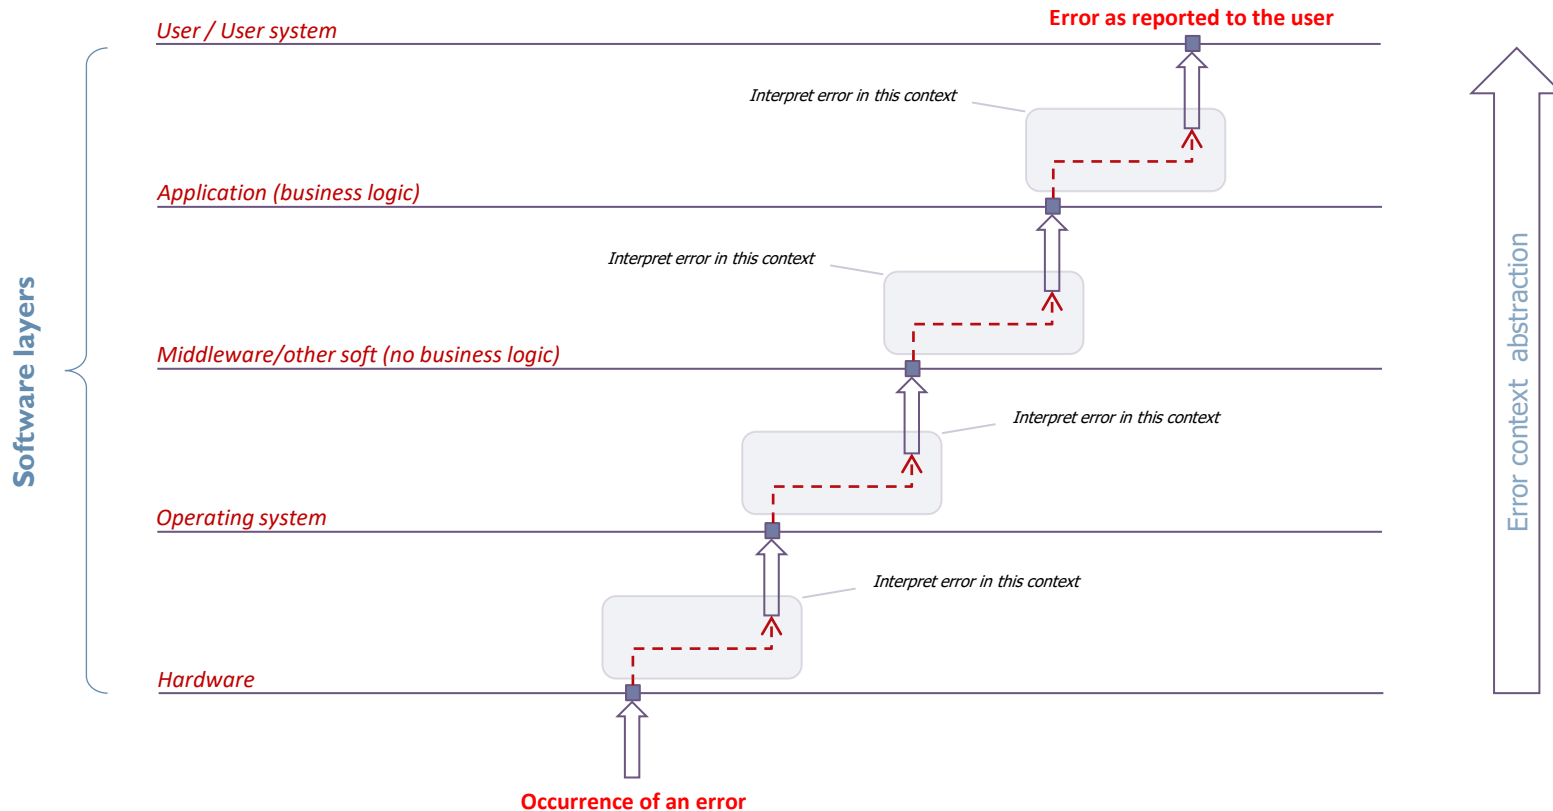

And software abstraction levels

# Table of content

---

- ▶ Software layers and error contexts
- ▶ Error abstraction logic
- ▶ Error abstraction example
- ▶ Error attributes I
- ▶ Error attributes II (continued)
- ▶ Multi-language support
- ▶ Error logical data model
- ▶ Error software development kit (SDK)

# Software layers and error contexts

# Error abstraction logic

---

- ▶ An error originating from a “lower” layer must be interpreted in the receiving layer context before transmitted to the “higher” layer(s).
- ▶ The business user (or system) must receive an error meaningful in his (its) business context
- ▶ In case of a user, the error must be human readable
- ▶ The **cascade of error interpretation must be navigable**
  - ▶ Each layer error interpretation are linked together (navigable both ways)

# Error abstraction example

---

- ▶ Hardware : A physical disk cannot be accessed
- ▶ OS : The file <filename> cannot be accessed
- ▶ Middleware (e.g. SOA) : The Contact Management service cannot be accessed
- ▶ Application : Impossible to update Mister X Contact infos.

There is no point in telling the final user that a physical disk cannot be accessed.

# Error attributes I

---

The following minimum set of error attributes is mandatory:

- ▶ A time stamp
  - ▶ Universal time if possible to allow reconciliation of errors originating from different technological stacks/systems (this supposes time synchronization between systems: may be legally required/binding)
- ▶ A unique error identifier
  - ▶ A globally unique one if possible (GUID)
  - ▶ Allows processing of the error by a system/application (automation)
- ▶ An origin reference
  - ▶ The component/module/function ... name triggering the error
  - ▶ A component/module/function origin identifier

# Error attributes II (continued)

---

- ▶ **A contextual information**
  - ▶ The action that was attempted or ...
  - ▶ The current logical context (e.g. in case of an event)
  - ▶ Human Readable
- ▶ **An error message**
  - ▶ As unambiguous as possible (e.g. no “an unknown error has occurred”)
  - ▶ Human readable
  - ▶ Multiple languages must be supported (at business level)

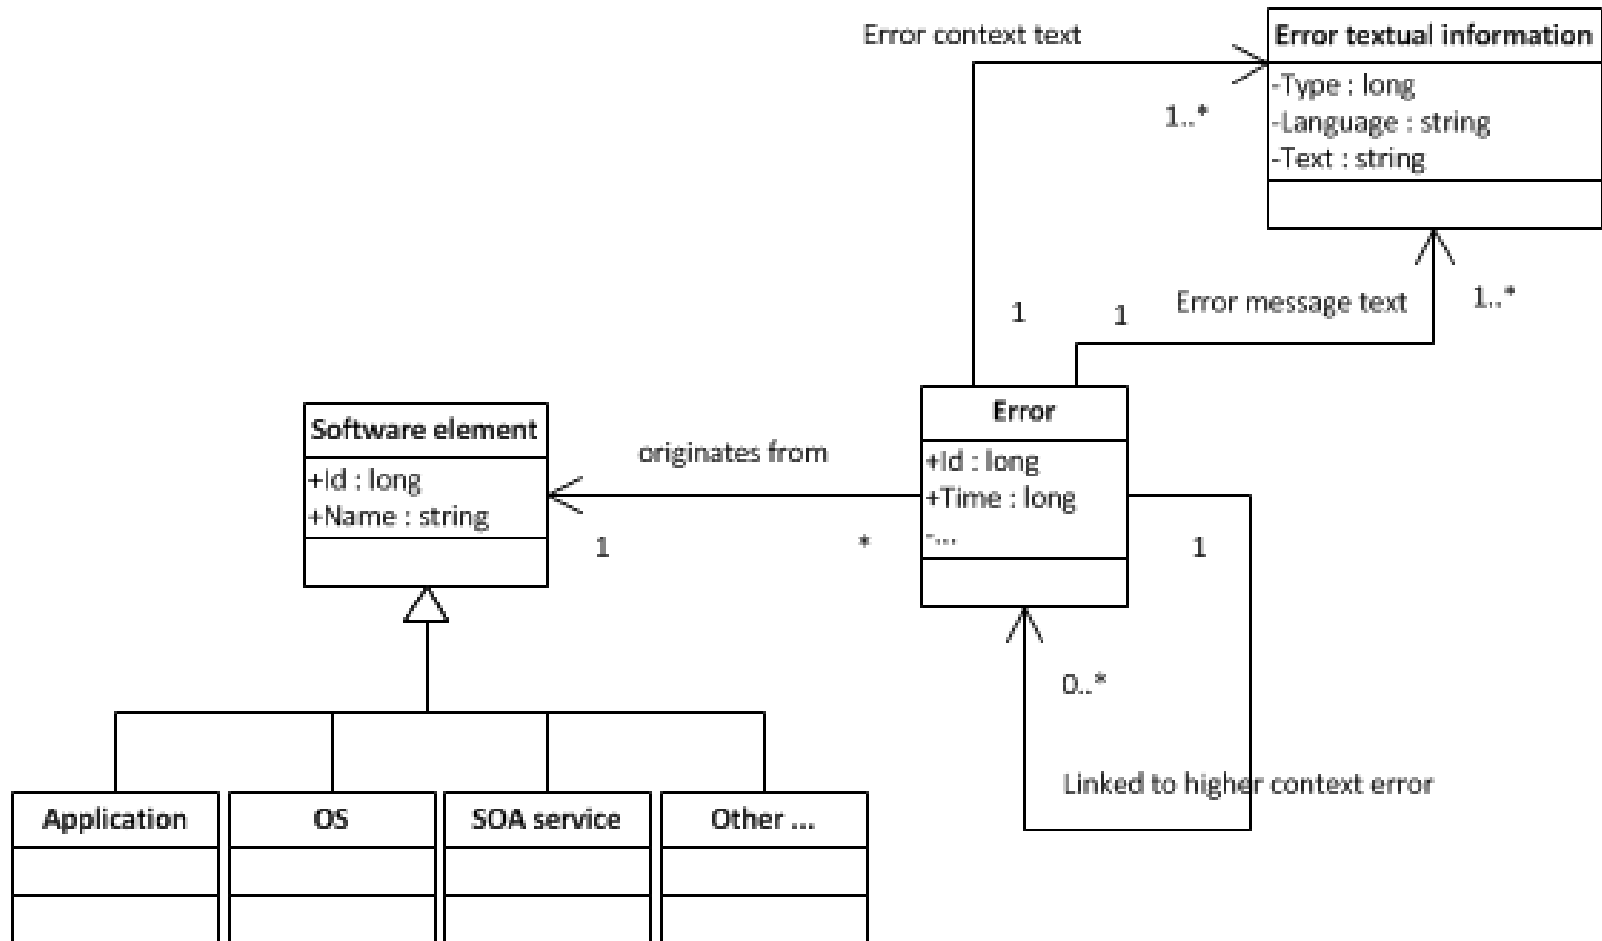

# Multi-language support

---

- ▶ Multiple languages must be supported for errors reporting to the business layer(s)
- ▶ Other software layers (non business) must all support one and unique coding language e.g. English
  - ▶ This relates to software engineering conventions and coding styles (name of variables and other software objects, database table and field names, etc)

# Error logical data model

# Error software development kit (SDK)

---

- ▶ Must be made available on each technological stacks
- ▶ Implements the same error handling logic (when applicable)

# End of presentation
